Operational explanation

(1) Collision

When the workpiece collides with the piston rod, the oil in the tube pushed by the piston is simultaneously pressurized. The pressurized oil passes through grooves on CKD's original slit orifice, and flows toward the oil chamber with an air chamber. The piston is further pressed in by cylinder thrust or workpiece weight, etc., but the area of the slit orifice gradually decreases, so that even higher resistance is generated. These series of operations are done continuously to stop the workpiece smoothly.

(2) Return

When released from the workpiece, the piston returns with the integrated spring. At this time it moves from the seal to the valve stopper, so that the oil return flow path is opened by the cutoff section on the piston. Oil passes through this flow path and the slit orifice and returns to the state before the workpiece collided. In this state, the system is on standby for the next workpiece collision.

Structural explanation

1. The slit orifice smoothly changes (decreases) as the piston moves as shown above.

This structure enables an ideal "stop" when used with a hydraulic damper, but as manufacturing is difficult, it has not been integrated in other brands. CKD has handled this tough issue with linear stopping performance as shown in Fig.1.

2. Generally, the dual tube shown above is used for the orifice area as a structure that changes with piston movement. Multiple small orifice holes in the inner pipe are closed as the piston moves. In this structure, performance via hole positioning precision is greatly affected, and resistance changes with each orifice, preventing smooth operation as shown in Fig. 2.
